Partial Fraction Decomposition by Division

Sidney H. Kung (sidneykung@yahoo.com) University of North Florida, Jacksonville FL 32224

In this note, we present a method for the partial fraction decomposition of two algebraic functions: (i) $f(x)/(ax+b)^t$ and (ii) $f(x)/(px^2+qx+r)^t$, where f(x) is a polynomial of degree n, t is a positive integer, and px^2+qx+r is an irreducible $(q^2 < 4pr)$ quadratic polynomial. Our algorithm is relatively simple in comparison with those given elsewhere [1, 2, 3, 4, 5, 6, 7, 8]. The essence of the method is to use repeated division to re-express the numerator polynomial in powers of the normalized denominator. Then upon further divisions, we obtain a sum of partial fractions in the form $A_i/(ax+b)^i$ or $(B_ix+C_i)/(px^2+qx+r)^j$ for the original function.

For (i), we let c = b/a, and express f(x) as follows:

$$f(x) = A_n(x+c)^n + A_{n-1}(x+c)^{n-1} + \dots + A_2(x+c)^2 + A_1(x+c) + A_0$$
$$= (x+c)[A_n(x+c)^{n-1} + A_{n-1}(x+c)^{n-2} + \dots + A_2(x+c) + A_1] + A_0,$$

where each A_i is a real coefficient to be determined. Then the remainder after we divide f(x) by x + c gives the value of A_0 . The quotient is

$$q_1(x) = (x+c)[A_n(x+c)^{n-2} + A_{n-1}(x+c)^{n-3} + \dots + A_3(x+c) + A_2] + A_1.$$

If we now divide $q_1(x)$ by x + c, we see that the next remainder is A_1 and the quotient is

$$q_2(x) = (x+c)[A_n(x+c)^{n-3} + A_{n-1}(x+c)^{n-4} + \dots + A_3] + A_2.$$

Continuing to divide in this manner n-1 times, we get the quotient $q_{n-1}(x) = A_n(x+c) + A_{n-1}$. Finally, dividing $q_{n-1}(x)$ by x+c, we obtain the last two coefficients, A_{n-1} and A_n . Thus, it follows that

$$\frac{f(x)}{(ax+b)^t} = \frac{1}{a^t} \left[\frac{A_n}{(x+c)^{t-n}} + \frac{A_{n-1}}{(x+c)^{t-n+1}} + \dots + \frac{A_1}{(x+c)^{t-1}} + \frac{A_0}{(x+c)^t} \right]. \tag{1}$$

For example, to find the partial fraction decomposition of $(x^4 + 2x^3 - x^2 + 5)/(2x - 1)^5$, we use c = -1/2 and perform synthetic division to obtain A_0 through A_n .

132

Substituting the coefficients into (1), we have

$$\frac{x^4 + 2x^3 - x^2 + 5}{(2x - 1)^5} = \frac{1}{2^5} \left[\frac{1}{(x - 1/2)} + \frac{4}{(x - 1/2)^2} + \frac{7/2}{(x - 1/2)^3} + \frac{1}{(x - 1/2)^4} + \frac{81/16}{(x - 1/2)^5} \right]$$

$$= \frac{1/16}{2x - 1} + \frac{1/2}{(2x - 1)^2} + \frac{7/8}{(2x - 1)^3}$$

$$+ \frac{1/2}{(2x - 1)^4} + \frac{81/16}{(2x - 1)^5}.$$

For (ii), we let u = q/p, v = r/p, and express f(x) in the following form:

$$f(x) = B_{(n-1)/2}(x^2 + ux + v)^{(n-1)/2} + B_{(n-3)/2}(x^2 + ux + v)^{(n-3)/2} + \cdots$$
$$+ B_1(x^2 + ux + v) + B_0,$$

where each coefficient B_k , k = 0, 1, ..., (n - 1)/2, is a linear function of x, and where we assume that $n \le 2t - 1$. In this case, dividing f(x) and each successive quotient by $x^2 + ux + v$ as described above, we obtain

$$\frac{f(x)}{(px^2 + qx + r)^t} = \frac{1}{p^t} \left[\frac{B_{(n-1)/2}}{(x^2 + ux + v)^{t - (n-1)/2}} + \frac{B_{(n-3)/2}}{(x^2 + ux + v)^{t - (n-3)/2}} + \dots + \frac{B_0}{(x^2 + ux + v)^t} \right].$$
(2)

For instance, take the rational function $(x^5 - 4x^4 + 3x^2 - 2)/(x^2 - x + 2)^3$. Then u = -1 and v = 2. Since (n - 1)/2 = 2, we let

$$x^5 - 4x^4 + 3x^2 - 2 = (Mx + N)(x^2 - x + 2)^2 + (Kx + L)(x^2 - x + 2) + Ix + J.$$

Since most students are not familiar with the synthetic division technique when the divisor is a quadratic polynomial, long division can be used in place of the following computation to find the coefficients I, J, K, L, M, and N.

VOL. 37, NO. 2, MARCH 2006 THE COLLEGE MATHEMATICS JOURNAL

Substituting the coefficients in (2) (note that t - (n-1)/2 = 1) gives

$$\frac{x^5 - 4x^4 + 3x^2 - 2}{(x^2 - x + 2)^3} = \frac{x - 2}{x^2 - x + 2} + \frac{-9x + 8}{(x^2 - x + 2)^2} + \frac{14x - 10}{(x^2 - x + 2)^3}.$$

Note also that $x^2 - x + 2 = (x - 1/2)^2 + 4/7$. On the right hand side of the above expression, replacing the coefficients -2, 8, and -10 in the numerators by -2 + 1/2M, 8 + 1/2M, and -10 + 1/2M, respectively, we get

$$\frac{x^5 - 4x^4 + 3x - 2}{((x - 1/2)^2 + 7/4)^3} = \frac{(x - 1/2) - 3/2}{(x - 1/2)^2 + 7/4} + \frac{-9(x - 1/2) + 7/4}{((x - 1/2)^2 + 7/4)^2} + \frac{14(x - 1/2)^2 - 3}{((x - 1/2)^2 + 7/4)^3}.$$

This last expression is an easily antidifferentiable form.

An Elegant Mode for Determining the Mode

D.S. Broca (dsbroca@iimk.ac.in), Indian Institute of Management Kozhikode, Kozhikode 673 571, Kerala, India

For any probability distribution, the mode, like the mean and median, is a measure of central tendency. Geometrically, it represents the relative maximum of the probability density function (pdf) and thus is the most striking feature in the curve's topogra-
